However , it can also be used to compare two columns in a model when filtering . To do this , you can use the split_part function in PostgreSQL to extract the domain from the e-mail address column . F () can be used to reference an existing column in a query . Django has a form of querying upgrading expression for several years : Expression F . This is often used for upgrading upgrading operations , such as incrementing an accountant . If there is a correspondence , this line will add the value of 1 to the aggregate . For example , we may be interested in users who have not connected from the first two weeks on the site . Now we know which email domains are associated with most users , to users who have logged on more recently and the percentage of users with this domain who have recently assets . Here caktusgroup.com has the most active registered users , but also has the most registered users in general . Ä © To get the popular domains , Ä "" we count the number of active users for a particular email domain . This requires the comparison of the value of the last_login column and date_join in the standard user model of contrib . auth : datetime import timedelta from django . contrib . auth . models import user of django . db . Models import f from django . utils . timezone import Now # Create some false data : 10 active users and 20 inactive today = now () activation_count = 10 inactive_count = 20 for i in the range ( 1 , activate_count + inactive_count + 1) : Activate = i
